(54) Title: A METHOD AND SYSTEM FOR ELECTRONIC BILL PAYMENT

(57) Abstract

A method and system for providing a fully automated electronic bill processing capability that is integrated with banking institutions and their customers is herein disclosed. The electronic bill payment system includes a community of payors (202), payees (208), payor banks, and payee banks (206) that are associated with computing systems that are interconnected by a computer network. A payor bank (206) receives electronic bills specifying payment requests from one or more payors (202) having an account at the payor bank. The payor bank (206) places a hold on the funds in the payor's account and then generates an electronic check (504) that is transmitted to the payee (208). The payee (208) receives an electronic check envelope that contains a number of electronic checks (504) that are encrypted and digitally signed by the payor bank. The payee generates an electronic deposit (506) including one or more endorsed electronic checks and a deposit slip. The electronic deposit (506) is encrypted and digitally signed by the payee (208). The electronic deposit is transmitted to a payee bank (206) that the payee is associated with. The payee bank authenticates the endorsed check and credits the payee's account accordingly.

A METHOD AND SYSTEM FOR ELECTRONIC BILL PAYMENT

This application is a continuation-in-part of serial no. 08/673,918 filed July 7, 1996. Application serial no. 08/673,918 is hereby incorporated by reference.

This invention relates to electronic communication systems and in particular to a method and apparatus for processing electronic bill payments between various financial institutions and clients connected by a network.

Background of the Invention

There is a great demand to support on-line business transactions in a fully automated closed-loop information and payment exchange system. The demand is especially present in banking and financial applications that are partially automated.

化氯化 网络大学生的 网络人名西克克尔 网络马克

For example, most banking institutions offer bill payment services through an outsourced third party. Fig. 1A shows one particular prior art bill payment system. A payor 100 sends an electronic mail message 101 authorizing an outsourced payment service 102 to pay one or more payees 104. The payment service 102 prints and mails a paper check on behalf of the payor 100 to each payee 104 specified by the payor 100. The payee 104 receives the paper check, endorses it, and deposits it with a bank 106 that the payee 104 is affiliated with. The payee's bank 106 clears the paper check with the payor's bank 110 through the Federal Reserve or local check clearing house organization 112.

NSDOCID: <WO 9826364A1 + >

5

10

15

5

20

25

30

Fig. 1B depicts a second prior art bill payment system. A payor 100 sends an electronic mail message 101 authorizing an outsourced payment service 102 to pay one or more payees 104. Typically, the payee is a large enterprise, such as a utility company. The payment service 102 collates several payments for a particular payor and sends to the payee's bank 106 an electronic check 117 that represents a lump sum payment. The electronic check 117 is received by the payee bank 106 and converted into a format 107 suitable for clearing with an Automatic Clearing House 108

The payee's bank 106 issues the formatted check 107 to the Automatic
Clearing House 108. The Automatic Clearing House 108 is part of the
Federal Reserve Net Settlement System. Finally, at the designated time of
day, the Automatic Clearing House 108 performs the check settlements and
eventually performs a funds transfer by sending a credit 111 to the payee's
bank 106 and a debit 109 to the payor's financial institution 110.

o samply and the first opening their will standen it to be not but we have with

Additionally, the payment service 102 mails to the payee 104 a paper print out 113 detailing the payments made to the payee through the Automated Clearing House 108.

,一点一点,一点,有一点,这是一点点。这种人的的是是一种,也是不是特殊的。

Although the prior art systems have worked well, they suffer a number of drawbacks. One problem with the system shown in Fig. 1A relates to the use of an intermediate outsourced service that relies on manual processing. The outsourced bill payment service 102 issues a paper check 103 that is mailed to the payee 104. The paper check 103 requires the payee 104 to physically deposit the check at the payee's bank 106. These steps increase the time that it takes for the payee 104 to receive payment. Another problem relates to the amount of time it takes to clear a transaction. Typically in the national system, funds are not settled for 2-3 days from the day the check is received by the institution. In order to assure the integrity and availability of funds, most institutions place holds on the availability of the funds until after checks clear. This causes inconveniences to both banks and end users:

1. Thursday 1995 Charles

The system shown in Fig. 1B, while using electronic checks, still requires substantial manual processing of payment information. What is needed is a fully automated bill payment system and method that is integrated with each banking institution and customer involved in a bill payment transaction.

or the country of the transfer and the country of the country of the first of the country of the

Fig. 1C illustrates a proposed prior art bill payment system that is currently under discussion although not yet realized. A payor 100 electronically pays one or more bills by transmitting an electronic check 115 to a payee 104 The payee 104 electronically deposits the electronic check 116 in the payee's bank 106. The payee bank 106 settles the electronic check 116 with the payor's bank 110 through an electronic check clearing process 114

and the contract of the first of the contract of

A shortcoming of the prior art system of Fig. 1C is that it requires each electronic check to be digitally signed by its respective payor. The payors, as 🛞 well as the banks and payees, must all be equipped with electronic check writing software and the appropriate hardware components, such as a Smart Card reader. The intended payor is the average consumer. It will take many years before this proposed system can be adopted by the average consumer and for the average personal computer to be equipped with a Smart Card reader. Also, having electronic checks generated by so many different parties inherently results in more mishaps and raises more issues of potential security breaches than "closed" systems where it is easier to verify the authenticity of payors and payees. Accordingly, there is a need for a more convenient means to facilitate electronic bill payment and one that has a greater assurance of security.

Summary of the Invention

the first property of the second of the seco

taria della della completa di constituira di constituira di constituira di constituira di constituira di const

The present invention pertains to an electronic bill payment system and method. The electronic bill payment system includes a community of payors, payees, payor banks, and payee banks that are associated with computing systems that are interconnected by a computer network.

10

15

20

25

30

A payor bank receives electronic bill payment authorizations specifying payment requests from various payors having client accounts at the payor bank. The payor bank places a hold on the funds in each payor's account and then generates an electronic check that is transmitted through the network to the payee. The payee receives an electronic check envelope through its electronic mail system that contains a number of electronic checks that are encrypted and digitally signed by the payor bank. The payee can receive multiple electronic check envelopes from different payor banks. The payee will process the payment it receives and updates its accounts receivable in the same manner that paper checks are processed. The payee generates an electronic deposit including one or more endorsed electronic checks and an electronic deposit slip. The electronic deposit is encrypted with the payee's digital certificate attached. The electronic deposit is transmitted through the network to the payee bank that the payee is associated with. The payee bank authenticates the endorsed check, clears the checks with the payor banks, and credits the payee's account . accordingly. Commence of the second control of the second

An intended application of the present invention is for Internet electronic commerce. Each payor bank has a web server that provides its customers or payors access to web pages. The web pages can be used to elicit from the payor one or more outstanding bill payments that are to be paid using the electronic bill payment system. Alternatively, a payor can request electronic bill payments through other remote interface access means such a voice menu system that is accessed via a telephone line.

Each of the electronic transactions that are generated in the electronic bill payment system are transmitted over the Internet or through other electronic message transmission channels. Each transaction utilizes a digital certificate and a cryptographic technique to secure the transaction. The electronic check includes the payor bank's digital certificate and information identifying the payor and the bill being paid. Each electronic deposit includes the

I therefore a gray William Con

payee's digital certificate and information identifying the payee account to be credited and the bill being paid. Each recipient of an electronic bill transaction verifies the received transaction before processing the transaction further.

Glossary

To assist the reader, the following glossary of terms used in this document is provided.

and the state of the

10

Payor. The party that requests electronic bill payment. For example, a payor can be a customer of a utility company. The payor interacts with the electronic bill payment system through a computing system and hence, the terms "payor" and "payor computer system" are used interchangeably.

15

Payee: The party that receives electronic payment. In the above example, the payee is the utility company. The payee interacts with the electronic bill payment system through a computing system and hence, the terms "payee" and "payee computer system" are used interchangeably.

,我们也没有一点,我们们就会一个好好,我们就不知道,我们就会会会的,这是一个我们的,我们也没有一个人。

20

25

Payor Bank: A bank or financial institution that handles the payor's banking or financial transactions. Preferably, the payor has an account established at the payor bank. The payor bank receives electronic bill payment instructions from the payor and submits an electronic check to the payee on behalf of the payor. The payor bank is associated with a computing system or financial transaction server that interfaces with the electronic bill payment system and processes the electronic bills. Hence, the term "payor bank" is used to refer to the associated computing system or financial transaction server.

30

Payee Bank: A bank or financial institution that handles the payee's banking or financial transactions. The payee has an account established at the payee bank. The payee bank receives electronic deposit slips from the

payee having one or more digitally endorsed checks that are deposited into the payee's account at the payee bank. The payee bank is associated with a computing system or financial transaction server that interfaces with the electronic bill payment system and processes the electronic deposits. Hence, the term "payee bank" is used to refer to the associated financial transaction server.

at the connected of the first and the states the states of the contract of the contract of the states of the state

Referring to Fig. 5, the present invention pertains to a distributed electronic bill payment system and method for Internet commerce. The distributed electronic bill payment system 200 includes a community of payors 202, payees 208, payor banks 206, and payee banks 206 that are associated with computing systems and interconnected by a public network, such as the Internet. An intended goal of the present invention is to minimize the number of parties requiring specialized resources (i.e., hardware and software) to utilize the electronic bill payment system 200. As such, the electronic bill payment system will have widespread application throughout the Internet community.

20

In a preferred embodiment of the present invention, one or more payors 202 access through the Internet, the Web server of an affiliated bank 206 at which the payor 202 maintains an account. The payor 202 can utilize a Web browser to view a Web page listing outstanding bills that can be electronically paid through the electronic payment system 200.

in the site of the first term of the contract of the contract

25

Alternatively, a payor 202 can use a dial-in telephone line to directly access the payor bank's electronic bill payment system. This option enables users without Internet access to utilize the electronic bill payment system.

30

The outstanding bills are transmitted to a payor bank 206 by one or more payees 208 affiliated with the electronic payment system 200. Typically,

· (1886年) 1986年 (1886年) 1987年 (1886年) 19874 (1886年) 19874 (18864) 19874 (18864) 19874 (18864) 19874 (18864) 19874 (18864) (18864) (18864) (18864) (18864) (18864) (18864) (18864) (18864) (18864) (18864) (18864) (18864) (18864) (18864) (1886

10

15

20

these payees can include utility companies, mortgage companies, and the like. Each payor has a respective bill mailbox 501 at the payor bank 206 that stores electronic bills 502 transmitted from these payees 208.

The Web browser allows each payor 202 to view the outstanding electronic bills 502 stored in the payor's bill mailbox 501. The Web browser also allows the payor 202 to formulate payment instructions 214 specifying the manner in which the electronic bills are to be paid, if at all. The electronic bill payment instructions 214 are transmitted to the payor bank 206 which then places a hold on the funds in the payor's account.

obligations are the president of the community of the com

The payor bank 206 then collects multiple checks for a particular payee 208 and transmits them to the payee 208 in an electronic check envelope 504. The payee 208 can receive multiple electronic check envelopes from different payor banks 206. The payee 208 will process the payment it receives and updates its accounts receivable in the same manner that paper checks are processed. The payee 208 generates an electronic deposit 506 including one or more endorsed electronic checks and an electronic deposit slip. The electronic deposit 506 is encrypted and the payee's digital certificate is attached to it. The electronic deposit 506 is transmitted through the network to the payee bank 206 that the payee is associated with. The payee bank 206 authenticates the endorsed check, clears the checks with the payor's bank 206, and credits the payee's account accordingly.

25

30

System Architecture

Referring now to Fig. 2, a distributed electronic payment system 200 according to the preferred embodiment of the present invention is shown.

The electronic payment system 200 can include one or more payors 202, one or more payees 208, one or more payor/payee banks 206 that are in

communication with each other through a variety of communication interfaces 205.

or an experimental control of the following from the St. I all a private problems are esti-

In some situations, a bank 206 handles the accounts of both the payors and the payees. In other cases, the bank 206 handles only the accounts of the payors and in yet another scenario the bank 206 can handle the accounts of only payees. For the purposes of this application, the description of a bank in the distributed electronic bill payment system is described for the case where the bank represents both payees and payors and is denoted as the payor/payee bank 206. However, this invention is not constrained to this particular implementation. A person skilled in the art can easily alter the features of the payor/payee bank 206 to accommodate either electronic bill payment processing scenario.

ostila neova esperante, a la principario prosesti sussilla di sello esperante la la companya de la companya de

The payor 202, payee 208, payor/payee bank 206 are associated with computer systems such as a personal computer, workstation, financial transaction server, and the like. A network interface 204 is provided that is a public network such as the Internet although any type of communications link or combination of communication links that enables electronic communication between the payor/payee bank 206 and one or more payees 208 and between the payor/payee bank 206 and one or more payors 202 can be employed. Alternatively, a payor 202 can also communicate directly with a payee/payor bank 206 through a remote access device 213 such as, but not limited to, a dial-up telephone line, via a remote access interface 210.

25

30

15

20

For the scenario where a bank represents different payors 202 and/or payees 208, the payor/payee bank 206 can communicate with other payor/payee banks 206 through an interbank communication interface 216 that is typically a private network. In addition, each payor/payee bank 206 has a legacy interface 215 for communication with an associated legacy system 217 (e.g., the bank's main frame computer system).

10 Fig. 5 illustrates the interactions between each party of the electronic payment system 200. The bill payment database 250 of each payor bank 206 maintains a bill mail box 501 or similar mechanism for each bill payment customer. Each customer's mail box 501 stores a list of pending bills, and may also list recently paid bills.

15

20

25

30

A payor 202 (i.e., a bank customer using the bill payment service of the present invention) interacts with a payor bank 206 by logging onto the payor bank's Web server, or direct dial computer connection, or telephone dial-in connection. Once the user has identified his/her account, has been authenticated by the payor bank 206 and has cleared a security check (e.g., by providing a password), the payor 202 can review the bills in his/her mail box 501, and can authorize payment of specified ones of the pending bills listed in the bill mail box 501. In the preferred embodiment, the payor 202 can authorize immediate payment or payment at a specified future date. A payor 202 can also go through a pre-selected list of payees 208 and indicate the amount to pay each payee 208.

Each electronic bill 502 in the payor's bill mail box 501 specifies one or more bill payments that the payor bank 206 is to process on behalf of the payor 202. Typically, each separate electronic bill 502 will have associated with it a single payment and a single payee along with remittance information that is described below. But in some instances a single electronic bill may

designate two or more payees 208 with a separate payments to each, such as an integrated telephone bill where two or more companies are providing services but are billing the payor 202 together.

[h.) eu i di. 30 83€66 D - 9,6 5 When the payor 202 authorizes payment of a specified electronic bill 502 าง ช่วากหุรการ เมืองการเกรียวสาดสมาชาย โดยการย (i.e., when the payor authorizes immediate payment or when the current date matches the previously authorized payment data for an electronic bill), the EVE SENSMINE payor bank 206 checks that the payor's account has sufficient funds to cover the bill payments and debits the payor's account accordingly. The payor 10 bank 206 then generates one or more electronic checks 504 on behalf of the payor 202. Each electronic check is digitally signed by the payor bank 206 and transmitted to the payee 208 designated by the corresponding electronic bill, preferably in electronic check envelopes. Enclosed in the electronic check envelope is the payor bank's digital certificate. Each electronic check 15 envelope 504 is used to transmit multiple electronic checks as a single ngatan gara ta panga is na lingga

Each payee 208 receives an electronic check envelope that contains several electronic checks from the same payor bank 206. The payee 208 processes each electronic check 504 and updates its accounting records accordingly. The payee may receive multiple electronic payments through the day. The payee 208 then generates an electronic deposit 506 that includes multiple endorsed checks and an electronic deposit slip 506. The endorsed checks and the electronic deposit slip 506 are then forwarded to the payee bank 206 for deposit in the payee's account.

The electronic check 504 is preferably the payment instrument developed by the Financial Services Technology Consortium (FSTC). It can contain the following information:

90 • payor identifier;

20

- payor bank identifier;
- payor's account number:

: :

5

10

15

- payee;
- payee bank identifier;
- an amount;
- date of the check; and
- one or more comment fields.

The electronic deposit 506 includes a deposit slip along with one or more checks. The deposit slip can contain the payee's account number, a timestamp of the transmission, and the payee's digital signature and certificate. The payee's digital signature, in effect, is the payee's endorsement of the deposited checks.

to bigliocides and letter through there is alsed of real particle to entire at the time.

The electronic transactions that are transmitted within the electronic bill payment system utilize a digital signal and certification protocol. Any of the well known digital signature and certification protocols can be used. A more detailed description of these protocols and techniques can be found in Schneider, Applied Cryptography, 2d ed., John Wiley & Sons, New York (1996), which is hereby incorporated by reference as background information.

的复数形式 医乳头 医动脉管 经收入股份 藍 海 医心管 医二氏管

Each electronic check 504 is "signed" with the payor bank's private key, encrypted, and then transmitted to the payee 208. The payee 208 decrypts the electronic check 504 and verifies the digital signature of the payor bank with the payor bank's public key. The electronic deposits are also digitally "signed" with the payee's private key 428, encrypted, and then transmitted to the payor bank 206. The payor bank 206 decrypts the electronic deposit and verifies the payee's digital signature with the payee's public key.

An advantage of the present invention is that only payees and banks (or other bill processing financial institutions) need to be equipped with the hardware and software necessary for generating electronic checks. As such, less parties in this distributed electronic payment system 200 are required to

en a laterature of the control

5

10

15

be equipped with the software and hardware which makes the system 200 easily adaptable for widespread commercial use.

Clearing and settlement of the electronic checks received by each payee bank 206 can be handled through electronic check clearing mechanisms such as the one described in U.S. patent application serial no. 08/673,918, filed July 1, 1996, which is hereby incorporated by reference.

Fig. 6 is a block diagram of the payor/payee bank 206 in a preferred embodiment of the present invention and will be described in more detail below. Fig. 7 illustrates the steps used by the payor/payee bank 206 in processing the electronic transactions. Referring to Figs. 6 and 7, each payor/payee bank 206 has a network interface 204 that enables the payor/payee bank 206 to receive and transmit transactions. Preferably, a payor 202 will transmit bill payment instructions to a payor bank 206 to pay bills 502 and the payor bank 206 transmits electronic checks to one or more payees 208. A payee 208 after receiving electronic checks from one or more payor banks 206, transmits electronic deposits 506 to a payee bank 206.

Referring to Figs. 2, 6 and 7, a Web server 228 is coupled to the network interface 204 of a payor/payee bank 206 and provides access for each payor 202 to request one or more electronic bill payment services through the Internet. Each payor bank's Web server 228 provides a payor 202 with one or more web pages 230 that the payor 202 uses to select one or more electronic bill payment services. Examples of such services include setting up a bill payment account (i.e., establishing a billmail box to which payees can send electronic bills), viewing outstanding bills that are pending payment, authorizing immediate or future payment of specified ones of the outstanding bills, and viewing previous electronic bill payments.

the Balana 1916 William a freezen by british in the green

I BENERAL COMPANIES OF A SECTION OF THE PROPERTY OF THE SECTION OF

The Web server 228 has access to a bill payment database 250 that stores data pertaining to each payor's bill payment account (i.e., the bill mail boxes 501 are associated with each payor).

Figs. 8A - 8B illustrate exemplary web pages that the bank's Web server 228 can provide to a payor 202. Referring to Figs. 2, 3, and 8A-8B, the payor 202 views the bank's web pages 230 through a web browser 314. One web page 802 can consist of a menu outlining the services that are provided to a payor 202. Another web page 804 can list each of the outstanding bills that are pending payment. A payment instruction field 806 is provided that allows the payor 202 to indicate the manner in which the payment is to be processed. Several options are available such as, but not limited to, the election to pay the payee 208 on a specified date, to hold the payment for a later date, to discard the payment and so on. The payment instructions 806 and other payment information are then formatted, encrypted, and transmitted to the Web server 228 to the front-end processor 232.

Alternatively, a payor 202 can communicate with the payor bank 206 through a remote access interface 210. The remote access interface 210 can be a dial-up telephone connected to a voice menu system. The voice menu system prompts the payor 202 for those pending bill payments that the payor 202 may wish to pay through the electronic bill payment system 200. The bill processor 236 formats the instructions into one or more electronic bills 502 that are forwarded to the front-end processor 232.

25

30

20

A front end processor 232 receives electronic transactions from one or more payors 202 and payees 208 (step 702) and performs an initial pre-processing of those transactions (step 704). The electronic transactions can consist of electronic bills 502 that are initiated from one or more payors 202 and electronic deposits 506 that are transmitted from one or more payees 208. Electronic deposit transactions are tested to determine whether they meet defined integrity criteria (e.g., verification of the associated digital signatures)

W. 1

AR WATER OWN TO SEE

and transaction requests not meeting those criteria are rejected. The integrity criteria are the same as or similar to conventional integrity criteria for electronic financial transactions and are not the subject of this document.

After the electronic transactions have been pre-processed by the front end processor 232, they are transferred to the appropriate processor 234 or 236 depending upon the transaction type. Electronic bills 502 or requests for bill payments are transferred to the bill processor 234 and electronic deposits 506 are transferred to the payment processor 236.

10

15

20

25

The payment processor 236 performs verification of the syntax of the electronic deposit slips and the endorsed electronic checks that are included in an electronic deposit 506. The electronic deposit slips and the endorsed electronic checks are then transferred to the settlement processor 238 (step 706). The primary function of the settlement processor 238 is to "clear and settle" each endorsed check. Since each endorsed check is associated with one of its own client or payee accounts, the transactions are forwarded to the "on-us" port 246 of its own bank in order that the payee's account is credited appropriately (step 706). The "on-us" port 246 of each bank couples the bank's internal transaction processing system 217 (or legacy system) with that of the payee bank's financial transaction server 206.

The bill processor 234 processes each received electronic bill 502. First, a check is made to determine if the payor's account has the requested funds (step 708). If the payor's account cannot satisfy the payment request, the payee 208 is notified of the insufficiency (step 710). Otherwise, an automatic transfer of the funds or the setting of a "hold" on equal amount of funds in the payee's account is made. The bill processor 234 then generates an electronic check 504 for the electronic bill payment (step 712).

30

Electronic checks 504 having a common payee are bundled into a "check envelope" (step 714) and transmitted to the payee 208 (step 716). Each

check envelope is an encrypted electronic message that holds a set of electronic checks that have been "signed" with the payor bank's digital signature. In one embodiment, the bill processor 234 will transmit the check envelopes in bundles at a pre-defined time in the day to the various payees 208 connected in the electronic payment system 200. In an alternate embodiment, packets of check envelopes are transferred to payees 208 more frequently, and in yet another alternative embodiment check envelopes are transferred between payees 208 continuously in real time.

The bill processor 234 uses a routing table 240 to determine the destination of the computing system that is associated with each payee 208 that is forwarded an electronic check envelope. The routing table 240 maps a payee's identifier into a network identifier suitable for routing the check envelopes.

15

20

5

The bill processor 234 then transmits to the settlement processor 238 a log specifying the checks that have been generated. The settlement processor 238 maintains an account balance with respect to each payor's account against which a transfer of funds was made and for each payee's account for which a credit of funds was made. The settlement processor 238 interacts with the appropriate payor and payee banks involved in each electronic bill payment in order to settle the transaction (step 718). A more detailed description of this settlement process is described in application serial no. 08/673,918.

25

Alternate Embodiments

While the present invention has been described with reference to a few specific embodiments, the description is illustrative of the invention and is not to be construed as to limiting the invention. Various modifications may occur

(;

 \mathcal{A}^{p}

a tradition many

to those skilled in the art without departing from the true spirit and scope of A lang aximaring by the the invention as defined by the appended claims. or with a residence of the residence of

Above the committee of the committee of the continue of For example, the electronic bill payment system can be modified so that any ment of the state of the ablace bank can receive electronic deposits from any payee regardless of whether the payee has a client account at the bank. In this case, the bank utilizes the settlement and processing system that is detailed in application serial no. arth 1900 at gradhhings allt researe i tarret ber bengg 08/673.918.

10 Moreover, the present invention has been described with each bank having the functionality of both a payee bank and a payor bank. However, the present invention is not limited to this configuration. A bank can be configured to represent the payee bank, payor bank, or both payor/payee bank.

15

20

Additionally, the present invention has been described with reference to a Web server and dial-up telephone line as the preferred means for requesting bill payments. However, the present invention is not limited to these means. A person skill in the art would be able to modify the present invention to utilize other technologies that provide a payor with the capability of initiating bill payments. Examples of such technologies include, but are not limited to, the use of phone transmissions through the Internet (e.g., WebTalk from Quaterdeck), electronic mail, a gopher server, a ftp server, etc.

25 Further, the method and system described hereinabove is amenable for execution on various types of executable mediums other than a memory device such as a random access memory. Other types of executable mediums can be used, such as but not limited to, a computer readable storage medium which can be any memory device, compact disc, or floppy and the second section of the second second second disk.

(54) Title: A METHOD AND SYSTEM FOR ELECTRONIC BILL PAYMENT

(57) Abstract

A method and system for providing a fully automated electronic bill processing capability that is integrated with banking institutions and their customers is herein disclosed. The electronic bill payment system includes a community of payors (202), payees (208), payor banks, and payee banks (206) that are associated with computing systems that are interconnected by a computer network. A payor bank (206) receives electronic bills specifying payment requests from one or more payors (202) having an account at the payor bank. The payor bank (206) places a hold on the funds in the payor's account and then generates an electronic check (504) that is transmitted to the payee (208). The payee (208) receives an electronic check envelope that contains a number of electronic checks (504) that are encrypted and digitally signed by the payor bank. The payee generates an electronic deposit (506) including one or more endorsed electronic checks and a deposit slip. The electronic deposit (506) is encrypted and digitally signed by the payee (208). The electronic deposit is transmitted to a payee bank (206) that the payee is associated with. The payee bank authenticates the endorsed check and credits the payee's account accordingly.

A METHOD AND SYSTEM FOR ELECTRONIC BILL PAYMENT

This application is a continuation-in-part of serial no. 08/673,918 filed July 7, 1996. Application serial no. 08/673,918 is hereby incorporated by reference.

This invention relates to electronic communication systems and in particular to a method and apparatus for processing electronic bill payments between various financial institutions and clients connected by a network.

5 Background of the Invention

There is a great demand to support on-line business transactions in a fully automated closed-loop information and payment exchange system. The demand is especially present in banking and financial applications that are partially automated.

For example, most banking institutions offer bill payment services through an outsourced third party. Fig. 1A shows one particular prior art bill payment system. A payor 100 sends an electronic mail message 101 authorizing an outsourced payment service 102 to pay one or more payees 104. The payment service 102 prints and mails a paper check on behalf of the payor 100 to each payee 104 specified by the payor 100. The payee 104 receives the paper check, endorses it, and deposits it with a bank 106 that the payee 104 is affiliated with. The payee's bank 106 clears the paper check with the payor's bank 110 through the Federal Reserve or local check clearing house organization 112.

NSDOCID: <WO___9826364A1_IA>

10

15

20

Fig. 1B depicts a second prior art bill payment system. A payor 100 sends an electronic mail message 101 authorizing an outsourced payment service 102 to pay one or more payees 104. Typically, the payee is a large enterprise, such as a utility company. The payment service 102 collates several payments for a particular payor and sends to the payee's bank 106 an electronic check 117 that represents a lump sum payment. The electronic check 117 is received by the payee bank 106 and converted into a format 107 suitable for clearing with an Automatic Clearing House 108.

The payee's bank 106 issues the formatted check 107 to the Automatic Clearing House 108. The Automatic Clearing House 108 is part of the Federal Reserve Net Settlement System. Finally, at the designated time of day, the Automatic Clearing House 108 performs the check settlements and eventually performs a funds transfer by sending a credit 111 to the payee's bank 106 and a debit 109 to the payor's financial institution 110.

Michael Parlia Continue a cintro esta constitución desta establista establista de 1900 especial.

Additionally, the payment service 102 mails to the payee 104 a paper print out 113 detailing the payments made to the payee through the Automated Clearing House 108.

20

25

30

5

Although the prior art systems have worked well, they suffer a number of drawbacks. One problem with the system shown in Fig. 1A relates to the use of an intermediate outsourced service that relies on manual processing. The outsourced bill payment service 102 issues a paper check 103 that is mailed to the payee 104. The paper check 103 requires the payee 104 to physically deposit the check at the payee's bank 106. These steps increase the time that it takes for the payee 104 to receive payment. Another problem relates to the amount of time it takes to clear a transaction. Typically in the national system, funds are not settled for 2-3 days from the day the check is received by the institution. In order to assure the integrity and availability of funds, most institutions place holds on the availability of the funds until after checks clear. This causes inconveniences to both banks and end users.

The system shown in Fig. 1B, while using electronic checks, still requires substantial manual processing of payment information. What is needed is a fully automated bill payment system and method that is integrated with each banking institution and customer involved in a bill payment transaction. tan 6.30 To protect the contract to be a mission and the contract the collection of the protect that the contract the contract that the contract the contract that the contrac

Fig. 1C illustrates a proposed prior art bill payment system that is currently under discussion although not yet realized. A payor 100 electronically pays one or more bills by transmitting an electronic check 115 to a payee 104. The payee 104 electronically deposits the electronic check 116 in the payee's bank 106. The payee bank 106 settles the electronic check 116 with the payor's bank 110 through an electronic check clearing process 114

tantina Auropinitum centro augeranti il meneralita meneralita in emergia. Europinita in legione si entre il en

A shortcoming of the prior art system of Fig. 1C is that it requires each electronic check to be digitally signed by its respective payor. The payors, as well as the banks and payees, must all be equipped with electronic check writing software and the appropriate hardware components, such as a Smart Card reader. The intended payor is the average consumer. It will take many years before this proposed system can be adopted by the average consumer * and for the average personal computer to be equipped with a Smart Card reader. Also, having electronic checks generated by so many different parties inherently results in more mishaps and raises more issues of potential security breaches than "closed" systems where it is easier to verify the authenticity of payors and payees. Accordingly, there is a need for a more convenient means to facilitate electronic bill payment and one that has a greater assurance of security.

Summary of the Invention

The present invention pertains to an electronic bill payment system and method. The electronic bill payment system includes a community of payors. 30 payees, payor banks, and payee banks that are associated with computing systems that are interconnected by a computer network.

10

15

20

25

30

A payor bank receives electronic bill payment authorizations specifying payment requests from various payors having client accounts at the payor bank. The payor bank places a hold on the funds in each payor's account and then generates an electronic check that is transmitted through the network to the payee. The payee receives an electronic check envelope through its electronic mail system that contains a number of electronic checks that are encrypted and digitally signed by the payor bank. The payee can receive multiple electronic check envelopes from different payor banks. The payee will process the payment it receives and updates its accounts receivable in the same manner that paper checks are processed. The payee generates an electronic deposit including one or more endorsed electronic checks and an electronic deposit slip. The electronic deposit is encrypted with the payee's digital certificate attached. The electronic deposit is transmitted through the network to the payee bank that the payee is associated with. The payee bank authenticates the endorsed check, clears the checks with the payor banks, and credits the payee's account accordingly.

An intended application of the present invention is for Internet electronic commerce. Each payor bank has a web server that provides its customers or payors access to web pages. The web pages can be used to elicit from the payor one or more outstanding bill payments that are to be paid using the electronic bill payment system. Alternatively, a payor can request electronic bill payments through other remote interface access means such a voice menu system that is accessed via a telephone line.

Each of the electronic transactions that are generated in the electronic bill payment system are transmitted over the Internet or through other electronic message transmission channels. Each transaction utilizes a digital certificate and a cryptographic technique to secure the transaction. The electronic check includes the payor bank's digital certificate and information identifying the payor and the bill being paid. Each electronic deposit includes the

Q.S.

payee's digital certificate and information identifying the payee account to be credited and the bill being paid. Each recipient of an electronic bill transaction verifies the received transaction before processing the transaction further.

10

Payor: The party that requests electronic bill payment. For example, a payor can be a customer of a utility company. The payor interacts with the electronic bill payment system through a computing system and hence, the terms "payor" and "payor computer system" are used interchangeably.

15

Payee: The party that receives electronic payment. In the above example, the payee is the utility company. The payee interacts with the electronic bill payment system through a computing system and hence, the terms "payee" and "payee computer system" are used interchangeably.

20

25

Payor Bank: A bank or financial institution that handles the payor's banking or financial transactions. Preferably, the payor has an account established at the payor bank. The payor bank receives electronic bill payment instructions from the payor and submits an electronic check to the payee on behalf of the payor. The payor bank is associated with a computing system or financial transaction server that interfaces with the electronic bill payment system and processes the electronic bills. Hence, the term "payor bank" is used to refer to the associated computing system or financial transaction server.

30

Payee Bank: A bank or financial institution that handles the payee's banking or financial transactions. The payee has an account established at the payee bank. The payee bank receives electronic deposit slips from the

5

payee having one or more digitally endorsed checks that are deposited into the payee's account at the payee bank. The payee bank is associated with a computing system or financial transaction server that interfaces with the electronic bill payment system and processes the electronic deposits. Hence, the term "payee bank" is used to refer to the associated financial transaction server.

si and natodi ciri ni maca uman na personia para neli edit pedenua di pidaza se <u>Overview</u>

10 Referring to Fig. 5, the present invention pertains to a distributed electronic bill payment system and method for Internet commerce. The distributed electronic bill payment system 200 includes a community of payors 202, payees 208, payor banks 206, and payee banks 206 that are associated with computing systems and interconnected by a public network, such as the Internet. An intended goal of the present invention is to minimize the number of parties requiring specialized resources (i.e., hardware and software) to utilize the electronic bill payment system 200. As such, the electronic bill payment system will have widespread application throughout the Internet community.

20

In a preferred embodiment of the present invention, one or more payors 202 access through the internet, the Web server of an affiliated bank 206 at which the payor 202 maintains an account. The payor 202 can utilize a Web browser to view a Web page listing outstanding bills that can be electronically paid through the electronic payment system 200.

25

Alternatively, a payor 202 can use a dial-in telephone line to directly access the payor bank's electronic bill payment system. This option enables users without Internet access to utilize the electronic bill payment system.

30

The outstanding bills are transmitted to a payor bank 206 by one or more payees 208 affiliated with the electronic payment system 200. Typically,

La Charles Carlotte Contraction of the contraction

these payees can include utility companies, mortgage companies, and the like. Each payor has a respective bill mailbox 501 at the payor bank 206 that stores electronic bills 502 transmitted from these payees 208.

The Web browser allows each payor 202 to view the outstanding electronic bills 502 stored in the payor's bill mailbox 501. The Web browser also allows the payor 202 to formulate payment instructions 214 specifying the manner in which the electronic bills are to be paid, if at all. The electronic bill payment instructions 214 are transmitted to the payor bank 206 which then places a hold on the funds in the payor's account.

or the same of the first are a state of

大學 (1995年) 1996年 - 新日本 新日本 新日本 1996年 - 1996年 -

The payor bank 206 then collects multiple checks for a particular payee 208 and transmits them to the payee 208 in an electronic check envelope 504. The payee 208 can receive multiple electronic check envelopes from different payor banks 206. The payee 208 will process the payment it receives and updates its accounts receivable in the same manner that paper checks are processed. The payee 208 generates an electronic deposit 506 including one or more endorsed electronic checks and an electronic deposit slip. The electronic deposit 506 is encrypted and the payee's digital certificate is attached to it. The electronic deposit 506 is transmitted through the network to the payee bank 206 that the payee is associated with. The payee bank 206 authenticates the endorsed check, clears the checks with the payor's bank 206, and credits the payee's account accordingly.

25

10

15

20

System Architecture

Referring now to Fig. 2, a distributed electronic payment system 200 according to the preferred embodiment of the present invention is shown.

The electronic payment system 200 can include one or more payors 202, one or more payees 208, one or more payor/payee banks 206 that are in

communication with each other through a variety of communication interfaces 205.

of the same of the above of the first property becomes

A TO LET TO SERVE AND AND AND THE REAL OFFICE AND ADMINISTRATION OF A SERVED ADMINISTRATION OF A SERVED

In some situations, a bank 206 handles the accounts of both the payors and the payees. In other cases, the bank 206 handles only the accounts of the payors and in yet another scenario the bank 206 can handle the accounts of only payees. For the purposes of this application, the description of a bank in the distributed electronic bill payment system is described for the case where the bank represents both payees and payors and is denoted as the payor/payee bank 206. However, this invention is not constrained to this particular implementation. A person skilled in the art can easily alter the features of the payor/payee bank 206 to accommodate either electronic bill payment processing scenario.

The payor 202, payee 208, payor/payee bank 206 are associated with computer systems such as a personal computer, workstation, financial transaction server, and the like. A network interface 204 is provided that is a public network such as the Internet although any type of communications link or combination of communication links that enables electronic communication between the payor/payee bank 206 and one or more payees 208 and between the payor/payee bank 206 and one or more payors 202 can be employed. Alternatively, a payor 202 can also communicate directly with a payee/payor bank 206 through a remote access device 213 such as, but not limited to, a dial-up telephone line, via a remote access interface 210.

25

For the scenario where a bank represents different payors 202 and/or payees 208, the payor/payee bank 206 can communicate with other payor/payee banks 206 through an interbank communication interface 216 that is typically a private network. In addition, each payor/payee bank 206 has a legacy interface 215 for communication with an associated legacy system 217 (e.g., the bank's main frame computer system).

WO 98/26364

5

A payor/payee bank 206 includes a central processing unit (CPU) 212, a user interface 214, a primary memory 218, and a secondary memory 220. The secondary memory 220 can store a bill payment database 250 that stores for each payor's account a "bill mail box" having information concerning pending bill payments and previously paid bills.

Francisco Contraction Contraction

The primary memory 218 of the payor/payee bank 206 can include the following:

- an operating system 222;
- - remote access interface procedures 226;
 - web server procedures 228;
 - web pages 230;
 - front end processor procedures 232;
- 15 bill processor procedures 234;
 - payment processor procedures 236;

randia no progresso di electrona della ammato del terrologico della segmenta. Editat

Fig. 5 illustrates the interactions between each party of the electronic payment system 200. The bill payment database 250 of each payor bank 206 maintains a bill mail box 501 or similar mechanism for each bill payment customer. Each customer's mail box 501 stores a list of pending bills, and may also list recently paid bills.

15

20

25

30

A payor 202 (i.e., a bank customer using the bill payment service of the present invention) interacts with a payor bank 206 by logging onto the payor bank's Web server, or direct dial computer connection, or telephone dial-in connection. Once the user has identified his/her account, has been authenticated by the payor bank 206 and has cleared a security check (e.g., by providing a password), the payor 202 can review the bills in his/her mail box 501, and can authorize payment of specified ones of the pending bills listed in the bill mail box 501. In the preferred embodiment, the payor 202 can authorize immediate payment or payment at a specified future date. A payor 202 can also go through a pre-selected list of payees 208 and indicate the amount to pay each payee 208.

A STATE OF THE STA

Each electronic bill 502 in the payor's bill mail box 501 specifies one or more bill payments that the payor bank 206 is to process on behalf of the payor 202. Typically, each separate electronic bill 502 will have associated with it a single payment and a single payee along with remittance information that is described below. But in some instances a single electronic bill may

designate two or more payees 208 with a separate payments to each, such as an integrated telephone bill where two or more companies are providing services but are billing the payor 202 together.

When the payor 202 authorizes payment of a specified electronic bill 502 (i.e., when the payor authorizes immediate payment or when the current date matches the previously authorized payment data for an electronic bill), the payor bank 206 checks that the payor's account has sufficient funds to cover the bill payments and debits the payor's account accordingly. The payor bank 206 then generates one or more electronic checks 504 on behalf of the payor 202. Each electronic check is digitally signed by the payor bank 206 and transmitted to the payee 208 designated by the corresponding electronic bill, preferably in electronic check envelopes. Enclosed in the electronic check envelope is the payor bank's digital certificate. Each electronic check envelope 504 is used to transmit multiple electronic checks as a single electronic message.

Each payee 208 receives an electronic check envelope that contains several electronic checks from the same payor bank 206. The payee 208 processes each electronic check 504 and updates its accounting records accordingly. The payee may receive multiple electronic payments through the day. The payee 208 then generates an electronic deposit 506 that includes multiple endorsed checks and an electronic deposit slip 506. The endorsed checks and the electronic deposit slip 506 are then forwarded to the payee bank 206 for deposit in the payee's account.

The electronic check 504 is preferably the payment instrument developed by the Financial Services Technology Consortium (FSTC). It can contain the following information:

30 • payor identifier;

20

25

- payor bank identifier:
- payor's account number;

15

way you go garage to get it

- o payee;
 - payee bank identifier;
- an amount;
- on date of the check; and
- 5 garage or more comment fields.

The electronic deposit 506 includes a deposit slip along with one or more checks. The deposit slip can contain the payee's account number, a timestamp of the transmission, and the payee's digital signature and certificate. The payee's digital signature, in effect, is the payee's endorsement of the deposited checks.

the Military for the Geography of the first and the property of the first of the first of the problem.

The electronic transactions that are transmitted within the electronic bill payment system utilize a digital signal and certification protocol. Any of the well known digital signature and certification protocols can be used. A more detailed description of these protocols and techniques can be found in Schneider, Applied Cryptography, 2d ed., John Wiley & Sons, New York (1996), which is hereby incorporated by reference as background information.

BANG I KAN TENNE TO I I I I I KAN KEMBELI

Each electronic check 504 is "signed" with the payor bank's private key, encrypted, and then transmitted to the payee 208. The payee 208 decrypts the electronic check 504 and verifies the digital signature of the payor bank with the payor bank's public key. The electronic deposits are also digitally "signed" with the payee's private key 428, encrypted, and then transmitted to the payor bank 206. The payor bank 206 decrypts the electronic deposit and verifies the payee's digital signature with the payee's public key.

An advantage of the present invention is that only payees and banks (or other bill processing financial institutions) need to be equipped with the hardware and software necessary for generating electronic checks. As such, less parties in this distributed electronic payment system 200 are required to

30

10

15

be equipped with the software and hardware which makes the system 200 easily adaptable for widespread commercial use.

Clearing and settlement of the electronic checks received by each payee bank 206 can be handled through electronic check clearing mechanisms such as the one described in U.S. patent application serial no. 08/673,918, filed July 1, 1996, which is hereby incorporated by reference.

en presidente a la como la la engela, en a vidado con entra colo do como entra el 1000 de programa.

Fig. 6 is a block diagram of the payor/payee bank 206 in a preferred embodiment of the present invention and will be described in more detail below. Fig. 7 illustrates the steps used by the payor/payee bank 206 in processing the electronic transactions. Referring to Figs. 6 and 7, each payor/payee bank 206 has a network interface 204 that enables the payor/payee bank 206 to receive and transmit transactions. Preferably, a payor 202 will transmit bill payment instructions to a payor bank 206 to pay bills 502 and the payor bank 206 transmits electronic checks to one or more payees 208. A payee 208 after receiving electronic checks from one or more payor banks 206, transmits electronic deposits 506 to a payee bank 206.

Referring to Figs. 2, 6 and 7, a Web server 228 is coupled to the network interface 204 of a payor/payee bank 206 and provides access for each payor 202 to request one or more electronic bill payment services through the Internet. Each payor bank's Web server 228 provides a payor 202 with one or more web pages 230 that the payor 202 uses to select one or more electronic bill payment services. Examples of such services include setting up a bill payment account (i.e., establishing a billmail box to which payees can send electronic bills), viewing outstanding bills that are pending payment, authorizing immediate or future payment of specified ones of the outstanding bills, and viewing previous electronic bill payments.

I taking a taking ing taking taking ang tahun tahun tahun bang ang tahun tahun tahun tahun tahun tahun tahun t

The Web server 228 has access to a bill payment database 250 that stores data pertaining to each payor's bill payment account (i.e., the bill mail boxes 501 are associated with each payor).

Figs. 8A - 8B illustrate exemplary web pages that the bank's Web server 228 can provide to a payor 202. Referring to Figs. 2, 3, and 8A-8B, the payor 202 views the bank's web pages 230 through a web browser 314. One web page 802 can consist of a menu outlining the services that are provided to a payor 202. Another web page 804 can list each of the outstanding bills that are pending payment. A payment instruction field 806 is provided that allows the payor 202 to indicate the manner in which the payment is to be processed. Several options are available such as, but not limited to, the election to pay the payee 208 on a specified date, to hold the payment for a later date, to discard the payment and so on. The payment instructions 806 and other payment information are then formatted, encrypted, and transmitted to the Web server 228 to the front-end processor 232.

Alternatively, a payor 202 can communicate with the payor bank 206 through a remote access interface 210. The remote access interface 210 can be a dial-up telephone connected to a voice menu system. The voice menu system prompts the payor 202 for those pending bill payments that the payor 202 may wish to pay through the electronic bill payment system 200. The bill processor 236 formats the instructions into one or more electronic bills 502 that are forwarded to the front-end processor 232.

25

30

20

A front end processor 232 receives electronic transactions from one or more payors 202 and payees 208 (step 702) and performs an initial pre-processing of those transactions (step 704). The electronic transactions can consist of electronic bills 502 that are initiated from one or more payors 202 and electronic deposits 506 that are transmitted from one or more payees 208. Electronic deposit transactions are tested to determine whether they meet defined integrity criteria (e.g., verification of the associated digital signatures)

É

15.

and transaction requests not meeting those criteria are rejected. The integrity criteria are the same as or similar to conventional integrity criteria for electronic financial transactions and are not the subject of this document.

After the electronic transactions have been pre-processed by the front end processor 232, they are transferred to the appropriate processor 234 or 236 depending upon the transaction type. Electronic bills 502 or requests for bill payments are transferred to the bill processor 234 and electronic deposits 506 are transferred to the payment processor 236.

10 the also been bendening at 202 been mountained been great A. Jellan, voic on Energy and

20

The payment processor 236 performs verification of the syntax of the electronic deposit slips and the endorsed electronic checks that are included in an electronic deposit 506. The electronic deposit slips and the endorsed electronic checks are then transferred to the settlement processor 238 (step-15 706). The primary function of the settlement processor 238 is to "clear and" settle" each endorsed check. Since each endorsed check is associated with one of its own client or payee accounts, the transactions are forwarded to the "on-us" port 246 of its own bank in order that the payee's account is credited appropriately (step 706). The "on-us" port 246 of each bank couples the bank's internal transaction processing system 217 (or legacy system) with that of the payee bank's financial transaction server 206.

The bill processor 234 processes each received electronic bill 502. First, a check is made to determine if the payor's account has the requested funds (step 708). If the payor's account cannot satisfy the payment request, the payee 208 is notified of the insufficiency (step 710). Otherwise, an automatic transfer of the funds or the setting of a "hold" on equal amount of funds in the payee's account is made. The bill processor 234 then generates an electronic check 504 for the electronic bill payment (step 712).

30

學大學 经工作 电电流放射 化二氯甲基

25

Electronic checks 504 having a common payee are bundled into a "check envelope" (step 714) and transmitted to the payee 208 (step 716). Each

check envelope is an encrypted electronic message that holds a set of electronic checks that have been "signed" with the payor bank's digital signature. In one embodiment, the bill processor 234 will transmit the check envelopes in bundles at a pre-defined time in the day to the various payees 208 connected in the electronic payment system 200. In an alternate embodiment, packets of check envelopes are transferred to payees 208 more frequently, and in yet another alternative embodiment check envelopes are transferred between payees 208 continuously in real time.

The bill processor 234 uses a routing table 240 to determine the destination of the computing system that is associated with each payee 208 that is forwarded an electronic check envelope. The routing table 240 maps a payee's identifier into a network identifier suitable for routing the check envelopes.

15

20

5

The bill processor 234 then transmits to the settlement processor 238 a log specifying the checks that have been generated. The settlement processor 238 maintains an account balance with respect to each payor's account against which a transfer of funds was made and for each payee's account for which a credit of funds was made. The settlement processor 238 interacts with the appropriate payor and payee banks involved in each electronic bill payment in order to settle the transaction (step 718). A more detailed description of this settlement process is described in application serial no. 08/673,918.

VISDOCID: >WO

Alternate Embodiments

While the present invention has been described with reference to a few specific embodiments, the description is illustrative of the invention and is not to be construed as to limiting the invention. Various modifications may occur

0.5

to those skilled in the art without departing from the true spirit and scope of the invention as defined by the appended claims.

Control of the Control of the Control of

For example, the electronic bill payment system can be modified so that any bank can receive electronic deposits from any payee regardless of whether the payee has a client account at the bank. In this case, the bank utilizes the settlement and processing system that is detailed in application serial no. 08/673,918.

Moreover, the present invention has been described with each bank having the functionality of both a payee bank and a payor bank. However, the present invention is not limited to this configuration. A bank can be configured to represent the payee bank, payor bank, or both payor/payee bank.

15

20

Additionally, the present invention has been described with reference to a Web server and dial-up telephone line as the preferred means for requesting bill payments. However, the present invention is not limited to these means. A person skill in the art would be able to modify the present invention to utilize other technologies that provide a payor with the capability of initiating bill payments. Examples of such technologies include, but are not limited to, the use of phone transmissions through the Internet (e.g., WebTalk from Quaterdeck), electronic mail, a gopher server, a ftp server, etc.

25 Further, the method and system described hereinabove is amenable for execution on various types of executable mediums other than a memory device such as a random access memory. Other types of executable mediums can be used, such as but not limited to, a computer readable storage medium which can be any memory device, compact disc, or floppy

WHAT IS CLAIMED:

1. An electronic financial transaction server, associated with a financial institution, comprising:

a memory for storing a plurality of client account data, each of a first subset of said client account data representing a payee associated with a payee client computer in communication with said electronic financial transaction server, each of a second subset of said client account data representing a payor associated with a payor client computer in communication with said electronic financial transaction server;

a communications interface for receiving one or more electronic bills from one or more of said payor client computers, each of said electronic bills having associated therewith a payee and a payee's financial institution; and

a bill processing mechanism that processes each of said electronic bills with respect to an associated client account data, said bill processing procedure including instructions to generate an electronic check for each of said electronic bills and to transmit said electronic check to an electronic financial server associated with a payee's financial institution.

20 2. The server of claim 1,

said communications interface further receiving one or more electronic deposits from one or more payee client computers, each of said electronic deposits having associated therewith a payee account identifier at said financial institution; and

a payment mechanism that processes each of said electronic deposits with respect to each said associated client account data.

3. The server of claim 1,

a settlement mechanism including instructions to update each client
account data associated with each said received electronic bill and each said
received electronic check deposit and to settle fund transfers associated with
each received electronic bill payment request and each received electronic
